- Sign into ARE portal.  
<https://are.nci.org.au/>
- Launch a VDI Desktop session:
  - Walltime = 1.5 hours
  - Queue = normalbw
  - Compute Size = small
  - Project = nf47
  - Storage = scratch/nf47
- Copy files
  - cd  
/scratch/nf47/<username>
  - mkdir OpenFOAM\_tut
  - cd OpenFOAM\_tut
  - cp -R /scratch/nf47/HPCD-CFD-OpenFOAM/\* .

The screenshot shows the 'VDI Desktop' configuration page in the ARE portal. The left sidebar lists 'Interactive Apps' with options: 'VDI Desktop - GPU-enabled', 'VDI Desktop' (selected), 'JupyterLab', 'RStudio', and 'RStudio (Rocky image)'. The main form fields are: 'Walltime (hours)' set to 1.5; 'Queue' set to 'normalbw'; 'Compute Size' set to 'small'; 'Project' set to 'nf47'; 'Storage' set to 'scratch/nf47'; and 'Software' set to 'gdata/nf47'. There is a checkbox for 'I would like to receive an email when the session starts' which is unchecked. Below the form is an 'Advanced options ...' section showing a 'SU estimate' of '2 cpu cores + 9GB mem on normalbw queue (1.25 SU/s/core/h) for 1.5h = 3.75 SUs'. A blue 'Launch' button is at the bottom right.

Home / My Interactive Sessions / VDI Desktop

**Interactive Apps**

- VDI Desktop - GPU-enabled
- VDI Desktop**
- JupyterLab
- RStudio
- RStudio (Rocky image)

**VDI Desktop**

Launch a regular desktop environment

**Walltime (hours)**

1.5

Number of hours your desktop can run (maximum). e.g. 1.5, 8, 24, 48

**Queue**

normalbw

**Compute Size**

small

Amount of CPU/Memory resources available to your desktop session

**Project**

nf47

Project to submit gadi job under; requires an SU allocation

**Storage**

scratch/nf47

gdata/nf47

**Software**

abacus abacus.mkl hdf ansys.moonsh ansys.mq ansys.nci ansys.mlt

☐ I would like to receive an email when the session starts

Advanced options ...

SU estimate  
2 cpu cores + 9GB mem on normalbw queue (1.25 SU/s/core/h) for 1.5h = 3.75 SUs

conditions

Numerical settings

Solving

Post-processing

- We will be simulating a floating object in a numerical wave tank.
- The object is tethered to the floor of the tank via a spring.
- A wave maker is used to generate regular Stokes II waves.
- For simplicity, the wave tank and object are treated as 2D.

- Momentum and continuity equations:

$$\frac{\partial(\rho \mathbf{U})}{\partial t} + \nabla \cdot (\rho \mathbf{U} \mathbf{U}) = -\nabla p + \rho \mathbf{g} + \nabla \cdot (\mu \nabla \mathbf{U}) - \mathbf{F}_s$$

$$\nabla \cdot \mathbf{U} = 0$$

$\mathbf{g}$  is gravitational acceleration and  $\mathbf{F}_s$  is surface tension force given by

$$\mathbf{F}_s = \sigma \kappa \mathbf{n}$$

$$n = \frac{\nabla \alpha_1}{|\nabla \alpha_1|}, \quad \kappa = \nabla \cdot \mathbf{n}$$

- A modified pressure field is used.

$$p_{rgh} = p - \rho \mathbf{g} \cdot \mathbf{x}$$

- The buoyancy terms on the right-hand side of the momentum equation can be expressed as

$$-\nabla p + \rho \mathbf{g} = -\nabla p_{rgh} - \mathbf{g} \cdot \mathbf{x} \nabla \rho$$

- Volume of fluid in a cell is specified through the field  $\alpha_1$  through an expression:

$$\forall_f = \alpha_1 \forall_{cell}$$

- If the cell is completely filled with fluid, then  $\alpha_1 = 1$ .
- Vice versa, the cell is filled with the void if  $\alpha_1 = 0$ .
- Volume of fluid is defined through a transport equation:

$$\frac{\partial \alpha_1}{\partial t} + \nabla \cdot (\alpha_1 \mathbf{U}) = 0$$

# Problem description

the steps

Case overview

Meshing

Models

Boundary and initial  
conditions

Numerical settings

Solving

Post-processing

- The compression of the surface is achieved by using the artificial compression term:

$$\nabla \cdot (\alpha_1(1 - \alpha_1)\mathbf{U}_r)$$

so that the VOF equation is

$$\frac{\partial \alpha_1}{\partial t} + \nabla \cdot (\alpha_1 \mathbf{U}) + \nabla \cdot (\alpha_1(1 - \alpha_1)\mathbf{U}_r) = 0$$

- The density is computed from the linear interpolation

$$\rho = \alpha_1 \rho_l + (1 - \alpha_1) \rho_g$$

Boundary and initial  
conditions

Numerical settings

Solving

Post-processing

- We are using OpenFOAM v2212, so load the appropriate module.
- A script, `Allrun` has been provided that executes all the required steps. Use `-p` as an argument to the script for parallel execution.
- A PBS batch script is also provided that will submit to a queue. This script takes care of loading the module.
- Suggest submitting the simulation now so it runs while we walk through the simulation setup.
- Approximate running time is 15 minutes.

**Meshing**

Models

Boundary and initial  
conditions

Numerical settings

Solving

Post-processing

- For meshing, we use `blockMesh`.  
Script: `runApplication blockMesh`
- `blockMesh` is a multi-block mesh generator.
- The mesh is generated from a dictionary file named `./system/blockMeshDict`.
- `blockMesh` generates high-quality meshes and it is the tool to use for very simple geometries.
- The effort and time required to set up the dictionary increases significantly as geometry complexity increases.

structure

The problem

Running the  
tutorial

Discussion on  
the steps

Case overview

Meshing

**Models**

Boundary and initial  
conditions

Numerical settings

Solving

Post-processing

- The wave conditions are input via the file `./constant/waveProperties`.
- We will be using regular waves with a Stokes II formulation.
- Wave height 0.12 m.
- Wave period 2.0 s.
- The wave inlet condition is ramped from flat water over a 2-second duration.
- The inlet patch uses one paddle.
- Wave absorption is enabled at the inlet to absorb any reflections.
- Absorption at the outlet uses shallow water theory.

Case overview

Meshing

Models

Boundary and initial  
conditions

Numerical settings

Solving

Post-processing

- It is very important to set the initial conditions to prescribe the initial state of the water.
- In order to initialise the volume fraction field to simulate a flat free surface at the time  $t = 0$ , The `setFields` utility is used.
- The `setFields` utility is responsible for the spatial distribution of the  $\alpha_1$  field by setting the desired value at the particular locations.
- For the water part of the domain, the value of the  $\alpha_1$  field is set to 1 and everywhere else is set to 0.
- `setFields` utility has the ability to specify desired regions in the form of boxes specified with two opposite nodes.

tutorial

Discussion on  
the steps

Case overview

Meshing

Models

Boundary and initial  
conditions

Numerical settings

Solving

Post-processing

- **interFoam** solver uses volume fraction specific solver settings:

```
solvers
{
    "alpha.water.*"
    {
        nAlphaCorr          2;
        nAlphaSubCycles     1;
        cAlpha               1;
        MULESCorr            yes;
        nLimiterIter         5;
        alphaApplyPrevCorr   yes;
        solver                smoothSolver;
        smoother              symGaussSeidel;
        tolerance            1e-8;
        relTol                0;
    }
}
```

- **nAlphaSubCycles**: Number of sub-cycles over the volume fraction equation in a given time step.
- **cAlpha**: Level of compression.
- **MULESCorr** implicit MULES

# Numerical settings: fvSolution

Regular waves  
interaction  
with a floating  
structure

The problem

Running the  
tutorial

Discussion on  
the steps

Case overview

Meshing

Models

Boundary and initial  
conditions

Numerical settings

Solving

Post-processing

- `interFoam` solver uses the PIMPLE algorithm:

PIMPLE

```
{  
    momentumPredictor      no;  
    nOuterCorrectors        1;  
    nCorrectors             3;  
    nNonOrthogonalCorrectors 1;  
    correctPhi              yes;  
}
```

- `momentumPredictor`: Don't solve the momentum equation. Just use it as a linearised predictor.
- `nOuterCorrectors`: PISO mode.

# Solving: controlDict

Regular waves  
interaction  
with a floating  
structure

The problem

Models

Boundary and initial  
conditions

Numerical settings

**Solving**

Post-processing

- Simulation parameters are defined in the dictionary `./system/controlDict`.

```
application      interFoam;
startFrom        latestTime;
startTime        0;
stopAt           endTime;
endTime          8;
deltaT           0.001;
writeControl      adjustableRunTime;
writeInterval     0.05;
purgeWrite       0;
writeFormat       binary;
writePrecision    6;
writeCompression no;
timeFormat        general;
timePrecision     6;
runTimeModifiable no;
adjustTimeStep    yes;
maxCo             0.5;
maxAlphaCo        0.5;
maxDeltaT         0.01;
```

# Solving: Execution

Regular waves  
interaction  
with a floating  
structure

The problem

Running the  
tutorial

Discussion on  
the steps

Case overview

Meshing

Models

Boundary and initial  
conditions

Numerical settings

**Solving**

Post-processing

- To run in parallel, we first decompose the mesh into a number of pieces matching the number of processors.

Script: `runApplication decomposePar`

- Execution of the solver.

Script: `runParallel interFoam`

# Post-processing: Function Objects

Meshing

Models

Boundary and initial  
conditions

Numerical settings

Solving

**Post-processing**

- Some post-processing can be done within the solver at run time using function objects.
- These are found at the bottom of the `controlDict`

```
functions
{
    sixDoF_History
    {
        type          sixDoFRigidBodyState;
        libs           ("libsixDoFRigidBodyState.so");
        angleFormat    degrees;
        writeControl    timeStep;
        writeInterval  5;
    }
}
```

# Post-processing: SixDof history
